## Abstract

We introduce  $n(n-1)/2$  natural involutions ("toggles") on the set  $S$  of noncrossing partitions  $\pi$  of size  $n$ , along with certain composite operations obtained by composing these involutions. We show that for many operations  $T$  of this kind, a surprisingly large family of functions  $f$  on  $S$  (including the function that sends  $\pi$  to the number of blocks of  $\pi$ ) exhibits the homomesy phenomenon: the average of  $f$  over the elements of a  $T$ -orbit is the same for all  $T$ -orbits. Our methods apply more broadly to toggle operations on independent sets of certain graphs.
